

# Lecture 7

## Stratified randomized experiments

# Outline

- Stratified randomized experiment
  - Fisher's exact p-value
  - Neyman's repeated sampling approach
  - Regression analysis
- Post stratification
- Suggested reading: Imbens and Rubin Chapter 9.1-9.6, Peng's book Chapter 5

# STAR (Student-Teacher Achievement Ratio) Project in Tennessee

(Mosteller. 1997. Bull. Am. Acad. Arts Sci.)

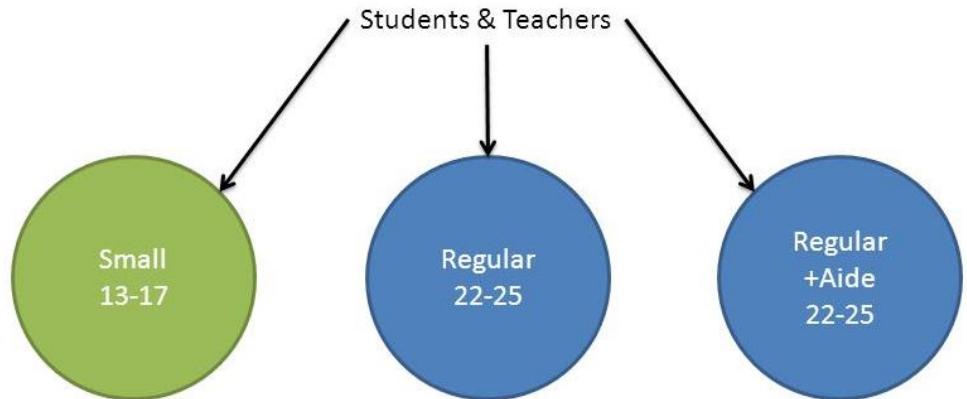

- **What is STAR? (1985-1989)**
  - A large-scale, four-year, longitudinal, experimental study of reduced class size
  - One the historically most important educational investigations
  - Cost of about \$12 million
  - Conclusion: small classes have an advantage over larger classes in reading and math in the early primary grades
- **Why was STAR needed?**
  - Legislators and school administrators doubted the significance of smaller classes
  - Conducted at the elementary-school level as this is where the foundation is laid for children's success in school.
  - The most credible study of class size

# STAR (Student-Teacher Achievement Ratio) Project in Tennessee

(Mosteller. 1997. Bull. Am. Acad. Arts Sci.)

- How is the experiment designed?
  - Three levels of “treatment”: three types of classes
    - Regular class + Aide:  
One teacher plus a full-time teacher’s aide.
    - Difference between Class Size and Pupil/Teacher Ratio
  - What need to be randomized, students or teacher?
    - Both students and teachers were randomly assigned to the one of the 3 arms
    - What is a unit, student or teacher?
      - The unit is a teacher in a class, instead of a student to avoid violation of no interference assumption

# The project STAR example

(Mosteller. 1997. Bull. Am. Acad. Arts Sci.)

- Two randomizations happen in the experiment
  - Randomization of teachers
  - Randomization of students
- Our causal analysis only relies on the randomization of teachers
  - The treatment effect on a particular teacher in a particular school is comparing the test score of being randomly assigned to a type of class and the test score of being randomly assigned to another type of class
- The randomization of students helps interpreting our results
  - Treatment effect between two arms can be explained by the classroom size difference instead of the systematic differences of students

# The project STAR example

(Mosteller. 1997. Bull. Am. Acad. Arts Sci.)

- How to conduct a large experiments across schools?
  - The study included 79 schools resulting in over 6,000 students per grade
  - potentially large differences in resources, teachers and students between schools
  - How to deal with that?
- Stratified randomization procedure
  - A school need to have a minimum of 57 students in kindergarten (at least one for each type of class)
  - Once a school is admitted, a decision was made on the number of classes per arm
  - Randomization within each school
    - Students and teachers within the school were randomly assigned to the one of the 3 arms

# The project STAR example

(Mosteller. 1997. Bull. Am. Acad. Arts Sci.)

- The interventions were initiated as the students entered school in kindergarten and continued through third grade.

	Kindergarten	Grade 1	Grade 2	Grade 3
Inner City	17	15	15	15
Suburban	16	15	15	15
Rural	38	38	38	38
Urban	8	8	7	7
<b>Total</b>	<b>79</b>	<b>76</b>	<b>75</b>	<b>75</b>

- Practical issues faced in real experiment
  - Longitudinal experiment
    - Schools may drop out of the project
    - Classes may gain/lose students so that can become too small or too big
  - Selection bias in students' involvement
    - Students' parents were informed so may want their children to be in the smaller class

**Table 9.1. Class Average Mathematics Scores from Project Star**

School/ Stratum	No. of Classes	Regular Classes $(W_i = 0)$	Small Classes $(W_i = 1)$
1	4	-0.197, 0.236	0.165, 0.321
2	4	0.117, 1.190	0.918, -0.202
3	5	-0.496, 0.225	0.341, 0.561, -0.059
4	4	-1.104, -0.956	-0.024, -0.450
5	4	-0.126, 0.106	-0.258, -0.083
6	4	-0.597, -0.495	1.151, 0.707
7	4	0.685, 0.270	0.077, 0.371
8	6	-0.934, -0.633	-0.870, -0.496, -0.444, 0.392
9	4	-0.891, -0.856	-0.568, -1.189
10	4	-0.473, -0.807	-0.727, -0.580
11	4	-0.383, 0.313	-0.533, 0.458
12	5	0.474, 0.140	1.001, 0.102, 0.484
13	4	0.205, 0.296	0.855, 0.509
14	4	0.742, 0.175	0.618, 0.978
15	4	-0.434, -0.293	-0.545, 0.234
16	4	0.355, -0.130	-0.240, -0.150
Average (S.D.)		-0.13 (0.56)	0.09 (0.61)

- We focus on two arms (regular classes v.s. small classes) and 16 schools that have at least two classes per arm

# Stratified randomized experiment

- Basic procedure:
  1. Blocking (Stratification): create groups of similar units based on pre-treatment covariates, let  $B_i \in \{1, \dots, J\}$  be the block indicator
  2. Block (Stratified) randomization: completely randomize treatment assignment within each group
- Blocking can improve the efficiency by minimizing the variance of the potential outcomes within each strata

*“Block what you can and randomize what you cannot”*

Box, et al. (2005). Statistics for Experimenters. 2nd eds. Wiley

- Assignment probability

$$P(\mathbf{W} = \mathbf{w} | \mathbf{X}) = \begin{cases} \prod_{j=1}^J \binom{N(j)}{N_t(j)}^{-1} & \text{if } \sum_{i:B_i=j}^N w_i = N_t(j) \text{ for } j = 1, \dots, J \\ 0 & \text{otherwise} \end{cases}$$

# Compare treated v.s. control? Simpson's paradox

- Compare the success rates of two treatment of kidney stores
- Treatment A: open surgery; treatment B: small puctures

	Treatment A	Treatment B
Small stones	<b>93%</b> (81/87)	87% (234/270)
Large stones	<b>73%</b> (192/263)	69% (55/80)
Both	78% (273/350)	<b>83%</b> (289/350)

- Large difference in treatment assignment probability across strata
  - Small stone: assignment probability  $\frac{87}{87+270} = 0.24$
  - Large stone: assignment probability is  $\frac{263}{263+80} = 0.77$
- Compare within each strata and take a weighted average:
  - True average causal effect:  $83.2\% - 78.2\% : (93\% - 87\%) \times 0.51 - (73\% - 69\%) \times 0.49$

# Fisher's exact p-value

- We still focus on the **Sharp null:**  $H_0: Y_i(0) \equiv Y_i(1)$  for all  $i = 1, \dots, N$
- **Choice of test statistics:**

Denote sample means for every strata / block

$$\bar{Y}_c^{\text{obs}}(j) = \frac{1}{N_c(j)} \sum_{i:G_i=j} (1 - W_i) \cdot Y_i^{\text{obs}}, \quad \bar{Y}_t^{\text{obs}}(j) = \frac{1}{N_t(j)} \sum_{i:G_i=j} W_i \cdot Y_i^{\text{obs}}$$

- Weighted combination of group mean differences across blocks

$$T^{\text{dif}, \lambda} = \left| \sum_{j=1}^J \lambda(j) \cdot (\bar{Y}_t^{\text{obs}}(j) - \bar{Y}_c^{\text{obs}}(j)) \right|$$

- Weights based on relative sample size  $\lambda(j) = \frac{N(j)}{N}$   
sample difference is more accurate in larger strata
- **“inverse-variance-weighting”:** assume that per-strata potential outcomes sample variances  $S_c^2(j) \equiv S_t^2(j) \equiv S^2$  for all  $j$ , then under stratified randomization

$$\mathbb{V}_W [\bar{Y}_t^{\text{obs}}(j) - \bar{Y}_c^{\text{obs}}(j) | \mathbf{Y}(0), \mathbf{Y}(1)] = S^2 \left( \frac{1}{N_c(j)} + \frac{1}{N_t(j)} \right)$$

# Fisher's exact p-value

- We still focus on the **Sharp null:**  $H_0: Y_i(0) \equiv Y_i(1)$  for all  $i = 1, \dots, N$
- **Choice of test statistics:**

Denote sample means for every strata / block

$$\bar{Y}_c^{\text{obs}}(j) = \frac{1}{N_c(j)} \sum_{i:G_i=j} (1 - W_i) \cdot Y_i^{\text{obs}}, \quad \bar{Y}_t^{\text{obs}}(j) = \frac{1}{N_t(j)} \sum_{i:G_i=j} W_i \cdot Y_i^{\text{obs}}$$

- Weighted combination of group mean differences across blocks

$$T^{\text{dif}, \lambda} = \left| \sum_{j=1}^J \lambda(j) \cdot (\bar{Y}_t^{\text{obs}}(j) - \bar{Y}_c^{\text{obs}}(j)) \right|$$

- Weights based on relative sample size  $\lambda(j) = \frac{N(j)}{N}$   
sample difference is more accurate in larger strata
- **“inverse-variance-weighting”:** weights

$$\lambda(j) = \frac{1}{\left( \frac{1}{N_c(j)} + \frac{1}{N_t(j)} \right)} / \sum_{k=1}^J \frac{1}{\left( \frac{1}{N_c(k)} + \frac{1}{N_t(k)} \right)}$$

# Fisher's exact p-value

- Can we simply use the two-sample mean difference statistic  $T = |\bar{Y}_t^{\text{obs}} - \bar{Y}_c^{\text{obs}}|$ ?
  - This is still one test statistic and we will still get valid Fisher's exact p-value if we follow the stratified randomization procedure to generate the reference distribution

Simpson's paradox:

- We may not always get small value of  $T$  even when the sharp null is true
  - Example:  
 $Y_i(0) \equiv Y_i(1) = 1$  for strata 1 and  $Y_i(0) \equiv Y_i(1) = 2$  for strata 2,  
 $N_c(1) = N_t(1) = 5$ ,  $N_c(2) = 15$  and  $N_t(2) = 5$   
Then  $\bar{Y}_t^{\text{obs}} = 1.5$  and  $\bar{Y}_c^{\text{obs}} = 1.75$
  - Power of the Fisher's test is affected

# Fisher's exact p-value and the project STAR

- Choice of test statistics:
  - Rank-based statistics
    - Get  $R_i^{\text{strat}}$  as the within-strata rank of each individual  $i$  (definition page 196 of Imbens and Rubin's book)
    - Average difference of within-strata ranks between treatment and control
$$|\bar{R}_t^{\text{strat}} - \bar{R}_c^{\text{strat}}|$$
  - Calculate the null distribution of test statistics
    - Randomly simulate treatment assignments following the same stratified randomization
- Project STAR results
  - P-values for the first 3 are similar as most schools have 4 classes
  - Large p-value for rank-based statistics as # classes too few in most schools

Test statistics	P-value
Weights $\lambda(j) = \frac{N(j)}{N}$	0.034
“inverse-variance-weighting”	0.023
$ \bar{Y}_t^{\text{obs}} - \bar{Y}_c^{\text{obs}} $	0.025
Rank-based statistics	0.15

# Neyman's repeated sampling approach

- **Target:** PATE or SATE  $\tau = \sum_j \frac{N(j)}{N} \tau(j)$  where  $\tau(j)$  is the PATE or SATE for strata  $j$
- **Analysis procedure**
  1. Apply Neyman's analysis to each strata / block

$$\hat{\tau}^{\text{dif}}(j) = \bar{Y}_{\text{t}}^{\text{obs}}(j) - \bar{Y}_{\text{c}}^{\text{obs}}(j), \quad \text{and} \quad \hat{V}^{\text{neyman}}(j) = \frac{s_{\text{c}}(j)^2}{N_{\text{c}}(j)} + \frac{s_{\text{t}}(j)^2}{N_{\text{t}}(j)}$$

- Variance estimator is conservative within each strata as discussed before
- 2. Aggregate block-specific estimates and variances
$$\hat{\tau}^{\text{strat}} = \sum_j \frac{N(j)}{N} \hat{\tau}^{\text{dif}}(j), \quad \hat{V}(\hat{\tau}^{\text{strat}}) = \sum_j \left( \frac{N(j)}{N} \right)^2 \hat{V}^{\text{neyman}}(j)$$
  - Both treatment assignments and potential outcomes are independent across strata
- 3. Statistical inference
  - Use normal approximation of the distribution of  $\hat{\tau}^{\text{strat}}$
  - Normal approximation works as long as  $N$  is large enough
    - Either small strata size with many strata or large strata size with few strata

# Power gain in Neyman's approach after stratification

- Variance decomposition

$$\underbrace{\mathbb{V}(X)}_{\text{total variance}} = \underbrace{\mathbb{E}\{\mathbb{V}(X | Y)\}}_{\text{within-block variance}} + \underbrace{\mathbb{V}\{\mathbb{E}(X | Y)\}}_{\text{across-block variance}}$$

- Assume that the treatment proportion  $\frac{N(j)}{N}$  is the same across all strata
  - Then  $\hat{\tau}^{\text{dif}} = \hat{\tau}^{\text{strat}}$
- $\mathbb{V}_{\text{complete}}(\hat{\tau}^{\text{dif}}) - \mathbb{V}_{\text{stratified}}(\hat{\tau}^{\text{strat}}) \geq 0$ 
  - Intuitively, we do not need to consider noise due to heterogeneity across blocks
  - For a rigorous proof, see Peng's book section 5.3.3
- Result in the project STAR
  - $\hat{\tau}^{\text{strat}} = 0.241$ ,  $\widehat{\mathbb{V}}(\hat{\tau}^{\text{strat}}) = 0.092^2$
  - (In correct) if we analyze as if it is a completely randomized experiment
    - $\hat{\tau}^{\text{dif}} = \bar{Y}_t^{\text{obs}} - \bar{Y}_c^{\text{obs}} = 0.224$  can be a biased estimate for  $\tau$
    - $\widehat{\mathbb{V}}(\hat{\tau}^{\text{dif}}) = 0.141^2$  larger standard deviation

# Linear regression

- Run separate linear regressions within each strata
  - Does not work if each strata size is too small
- Denote  $B_i(j)$  as the indicator variable of whether sample  $i$  belong to strata  $j$
- If there are no covariates, equivalently, we can write separate linear regression models into a joint regression model

$$Y_i^{\text{obs}} = \alpha_j + \tau(j)W_i + \varepsilon_i$$

- The underlying model for the potential outcomes

$$\mathbb{E}[Y_i(w)|\{B_i(j), j = 1, \dots, J\}] = \alpha_j + \tau(j)w$$

- Average causal effect for strata  $j$  is  $\tau(j)$
- The strata indicators  $B_i(j)$  are treated as pre-treatment covariates
- We need to adjust for the strata indicators as we only have conditional independence

$$(\mathbf{Y}(0), \mathbf{Y}(1)) \perp \mathbf{W} | \mathbf{B}(j)$$

- The homoscedastic error assumption for the joint model is assuming that
$$\mathbb{V}[Y_i(0)|\{B_i(j), j = 1, \dots, J\}] = \mathbb{V}[Y_i(1)|\{B_i(j), j = 1, \dots, J\}] = \sigma^2$$

# Post-stratification

- In a completely randomized experiment, each assignment vector has the sample probability ( $P(\mathbf{W} = \mathbf{w})$ ) if  $\sum_{i=1}^N w_i = N_t$
- If we focus on a subgroup  $S$ , conditional on  $N_{t,S} = \sum_{i \in S} W_i$ , the assignment vector for the individuals in the subgroup also has the same probability ( $P(\mathbf{W}_S = \mathbf{w}_S)$ ) if  $\sum_{i \in S} w_i = N_{t,S}$
- So conditional on  $N_{t,S}$ , we can treat the treatment assignment as from a completely randomized experiment also for the subgroup
- Post-stratification (Miratrix. et al. 1971. J. Royal Stat. Soc. B.)
  - Blocking after the experiment is conducted
  - Analyze the experiment as from a stratified randomized experiment by conditioning on  $N_{t,S}$  for each strata  $S$
  - By post-stratification, we can stratify individuals into relatively homogenous subpopulations
  - Post-stratification is nearly as efficient as pre-randomization blocking

# Meinert et. al. (1970)'s example

- A completely randomized experiment.
- Treatment is tolbutamide ( $Z = 1$ ) and control is a placebo ( $Z = 0$ )
- Causal effect: difference in the survival probability

Age < 55		Age $\geq 55$	
	Surviving	Dead	
$Z = 1$	98	8	$Z = 1$
$Z = 0$	115	5	$Z = 0$
Total			
	Surviving	Dead	
$Z = 1$	174	30	
$Z = 0$	184	21	

Peng's book Section 5.4.1
